

None of these three is a result: agents 1 and 2 of a matched pairing get identical prompts, the ten replicates share a prompt, and the cell means should reproduce across a random split of the dyads. Agent 2 cooperates 0.017 less than agent 1 on average, a position artefact worth carrying into any claim that rests on a single role. Panel b's ratio is the observed spread over what independent rounds would give; above 1 means rounds within a game are correlated, which is why every interval in this suite resamples whole dyads.
