

a**b****c**

Both coordinates need the opponent to have played C and D at least once, so the 3,171 agent-games plotted are those where both are estimable; the lattice in a is small denominators over ten rounds, not clustering. WSLS is deliberately not a corner: it needs the player's own last action, so anything in the interior is stochastic, deeper than memory-one, or both. Panel c splits the ten replicates of each condition in half and re-estimates both coordinates; a position that is a property of the condition reproduces, one that is a property of the run does not.
